NONMEM provides a flexible library of pre-written models to solve pharmacokinetic problems. This library is called PREDD (PREDictions for Population Pharmacokinetics). Using PREDPP requires 3 separate records:
\$SUBR specifies the PREDPP subroutine to use and how it should be parameterised
\$PK specifies the individual PK parameters. Typically this involves a fixed effect model for the covariate effects and a random effects model for population parameter variability. The names of the individual parameters are pre-defined in PREDPP and must match those indicated in \$SUBR
\$ERROR returns the model prediction (F) with a model for the residual error random effect

NM-TRAN and NONMEM

©NHG Holford, 2017. All rights reserved.

Nearly all users are familiar with NONMEM through files used by NM-TRAN. Learning how to provide the input to NONMEM is really learning how to provide input to NM-TRAN. NM-TRAN then translates the input into a format used by NONMEM to do the modelling.

Slide
4

The connection between NM-TRAN and NONMEM is quite complex. It involves the use of a Fortran compiler to turn a Fortran source file (FSUBS) into an object file which can be linked with the main NONMEM and PREDDPP object files. Because NONMEM and PREDDPP are pre-compiled this makes the creation of a NONMEM executable model very quick. NM-TRAN also rewrites its input data file into a format suitable for NONMEM (FDATA) and creates a control stream that tells NONMEM what to do (FCON).

PREDDPP ADVAN Subroutines

ADVAN1 One Compartment Linear Model
ADVAN2 One Compartment Linear Model with First Order Absorption
ADVAN3 Two Compartment Linear Model
ADVAN4 Two Compartment Linear Model with First Order Absorption

ADVAN5 General Linear Model
ADVAN6 General Nonlinear Model
ADVAN7 General Linear Model with Real Eigenvalues
ADVAN8 General Nonlinear Model with Stiff Differential Equations
ADVAN9 General Nonlinear Model with Equilibrium Compartments
ADVAN10 One Compartment Model with Michaelis-Menten Elimination

ADVAN11 Three Compartment Linear Model
ADVAN12 Three Compartment Linear Model with First Order Absorption
ADVAN13 General Nonlinear Model (usually better than ADVAN6) (NM7)
ADVAN15 General Nonlinear Model with Equilibrium Compartments (NM7.4.1)

The most commonly used PREDDPP subroutines are shown in bold. They are named ADVAN subroutines because they advance the solution of the model from one record in the data file to the next in time sequence. This is a clever way of allowing arbitrary dosing patterns. There are some shortcuts for specifying regular dosing patterns which can aid in making the input data file simpler in structure. ADVAN7 may be faster than ADVAN5. Most PK models have real eigenvalues. The ADVAN6 subroutine allows the user to write their own model in differential equations. This is quite general (just like other programs such as Berkeley Madonna or WinNonLin). The models are not restricted to PK problems but can be used to solve any kind of model defined by ordinary differential equations. ADVAN13 and ADVAN15 may be faster with the newer NM7 estimation methods.

PREDDPP TRAN Subroutines Basic PK Parameters

TRANS1 Dummy, or null, translator; (K,V)
TRANS2 Used with ADVAN1 and ADVAN2 (CL,V).
TRANS3 Used with ADVAN3 and ADVAN4 (CL,V,Q,VSS).
TRANS4 Used with ADVAN3, ADVAN4(CL,V1,Q,V2)
TRANS4 Used with ADVAN11, ADVAN12 (CL,V1,Q2,V2,Q3,V3)
TRANS5 Used with ADVAN3 and ADVAN4 (AOB, ALPHA, BETA)
TRANS6 Used with ADVAN3, ADVAN4, ADVAN11, ADVAN12 (ALPHA, BETA, K21)

The TRAN subroutines are options specified for each ADVAN subroutine. They determine the parameters that need to be defined in \$PK. In most cases the CL and V parameterisation is preferred for population analysis.

PREDPP Additional PK Parameters

Scale parameters S_n , e.g.: S1 S2 S3 S4 SC S0
Bio-availability fractions F_n , e.g.: F1 F2 F3
Output fractions F_n , e.g.: F2 F3 F4 F0 FO
Infusion rates R_n , e.g.: R1 R2 R3
Infusion durations D_n , e.g.: D1 D2 D3
Absorption lags $ALAG_n$, e.g.: ALAG1 ALAG2 ALAG3
Time scale: TSCALE (may be written XSCALE)
Model event times $MTIME(i)$, e.g.: $MTIME(1)$ $MTIME(2)$

Each of the ADVAN subroutines has additional PK parameters. These are typically associated with particular compartments of the PK model by a numeric suffix e.g. the bioavailability of doses put into compartment one is F1 and into compartment two is F2. The scale parameters control how the amounts in each compartment are used to create the F prediction variable used by \$ERROR. Most commonly the scale parameter is the volume of distribution so that F which is always calculated from the amount divided by the compartment scale ($A(n)/S_n$) becomes the concentration predicted in that compartment. Note that F is the compartment prediction in \$ERROR. It has nothing to do with the F1, ..., F_n bioavailability fractions which are defined in \$PK. Zero-order input models need a RATE data item in the data set. This defines the rate of input. The duration will then be determined by the AMT available for input. If the RATE data item is -1 this is special value which means the rate will be specified in \$PK by the R1, ..., R_n compartment specific rate item. If the RATE item is -2 then \$PK provided the D1, ..., D_n compartment specific duration of the input. This means either the rate or the duration can be estimated as a parameter. Most commonly it is the duration which is estimated. Lag times for absorption are defined by the ALAG1, ..., ALAGn compartment specific lag time. Output fractions and time scale parameters are very rarely used. Output fractions in the format F2, F3, F4, etc can only refer to the compartment number after the largest disposition compartment e.g. F2 for 1 cpt model, F3 for a 2 cpt model and F4 for a 3 cpt model. F0 and FO are synonyms for the output compartment.

PREDPP Data Items

- TIME +/- DATE or DAT1
- AMT Dose
- CMT Dose compartment
- RATE Dose rate (-1 with R_n , -2 with D_n)
- SS 0=no 1=yes 2=add SS dose regimens
- II Interdose Interval
- ADDL Additional Doses

©NHQ Horford, 2017, all rights reserved.

Dosing for PREDPP models is controlled by special data items. It is possible to use DATE e.g. 12/31/2008 with a TIME e.g. 10:30 to specify the TIME of a record. NM-TRAN converts the date and time values into hours from the first record for each subject. This works for \$PRED as well as PREDPP models. The dose to be put into a compartment is indicated by the AMT data item. It is usually helpful to make the units of the dose match those of the predicted concentrations e.g. specify AMT in micrograms if the concentration measurements are micrograms/L. This is not necessary but typically helps reduce confusion about the meaning of parameters. The CMT data item indicates which compartment the AMT should be put into. This item is not required but is

		<p>often useful. The default value is typically compartment 1.</p> <p>The RATE data item is frequently set to -2 so that the duration of a zero order input can be estimated. It is only needed for zero-order input models.</p> <p>The SS and ADDL data items must be combined with II. They can be used to make the data set simpler if you can assume that doses are given at regular intervals (defined by II). You can assume that steady state has been reached using SS or you can specify the number of additional doses to be added to the system after the dosing record with a positive ADDL value.</p> <p>SS=2 may be used with a second dose record to combine 2 SS dosing regimens e.g. 500 mg q24 morning and 1000 mg q24 evening.</p>
